UI/UX Design and Prototyping

MediCare | Website interface concept and design guidelines

DEPI Graduation Project | Full Stack .NET Track

Design objective

Create a clear, reassuring clinic experience that helps patients find doctors and book appointments, while giving doctors and administrators efficient tools for their work. The following low-fidelity desktop wireframes describe the primary screens and interaction hierarchy; they are design proposals for the team to implement and validate.

Experience principles

• Make the next step obvious: search, choose a time, confirm.

• Use plain language for appointment status, validation, and errors.

• Keep patient, doctor, and administrator workflows distinct by role.

• Show only information needed for the current task; protect sensitive medical details.

• Support mobile-first access and maintain consistent navigation.

Color palette

Inspired by the supplied deep-red and gold brand reference. Use gold as a restrained accent, not for small body text.

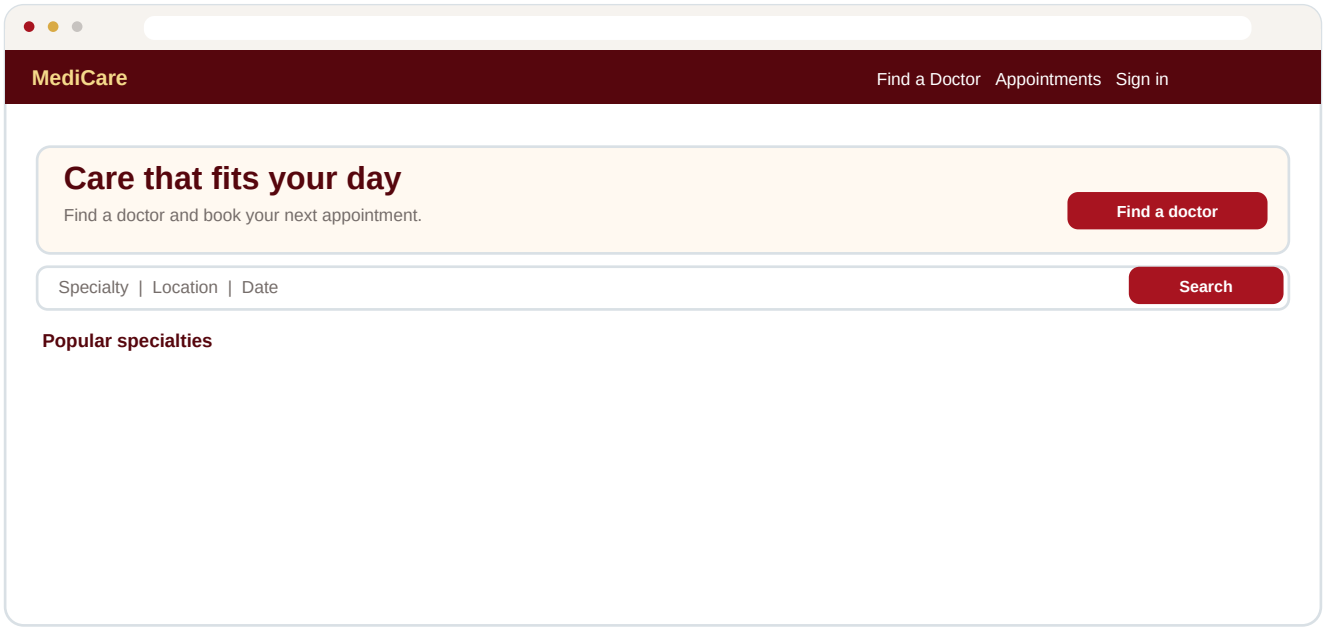
Token	Hex	Recommended use
Primary burgundy	#56060D	Brand header, navigation, footer
Action crimson	#A81420	Primary buttons, active links, key actions
Warm gold	#D9AA45	Small icons, borders, active markers
Champagne	#F5D98A	Soft highlight fills and selected states
Warm ivory	#FFF9F1	Page background and subtle panels
White	#FFFFFF	Cards, forms, primary content surfaces
Charcoal	#292526	Body text and labels
Muted gray	#756D6A	Secondary labels and help text

Typography and components

Use a legible sans-serif such as Inter, Segoe UI, or system-ui for interface text. Reserve a restrained serif treatment for the wordmark only if it matches the supplied logo. Use clear heading levels, consistent button styles, form labels above inputs, and visible keyboard focus.

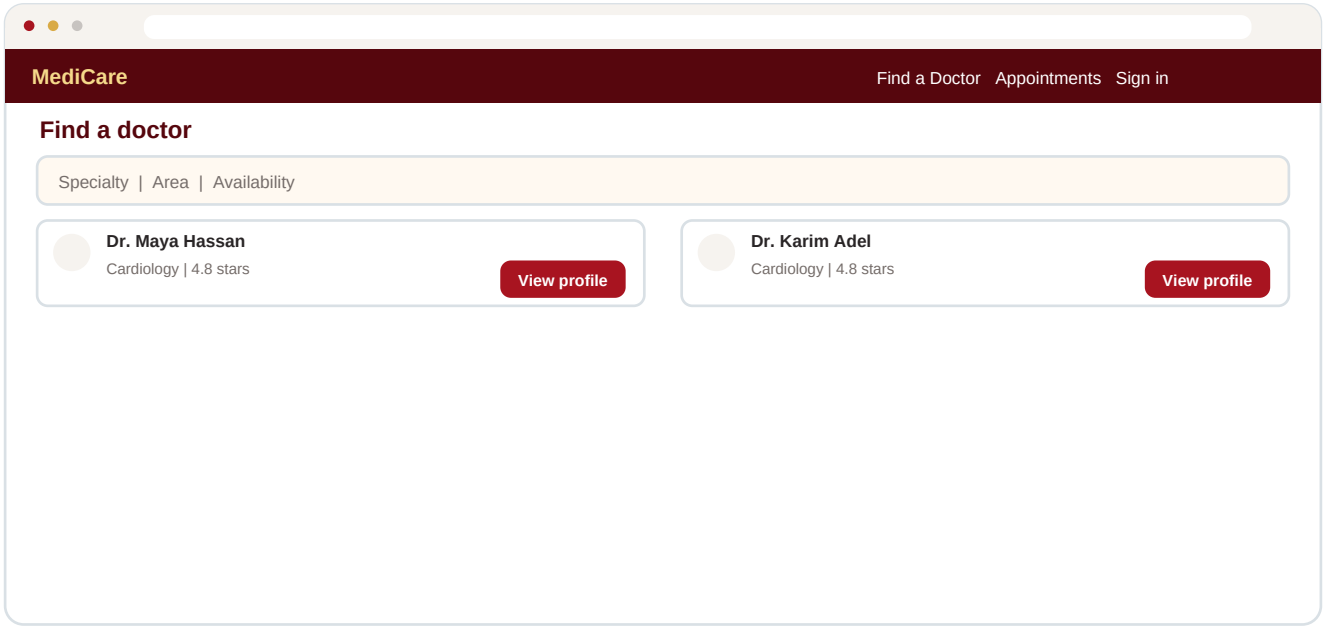
Patient landing page

Primary entry point: one prominent doctor search action, concise hero copy, and a short list of popular specialties.



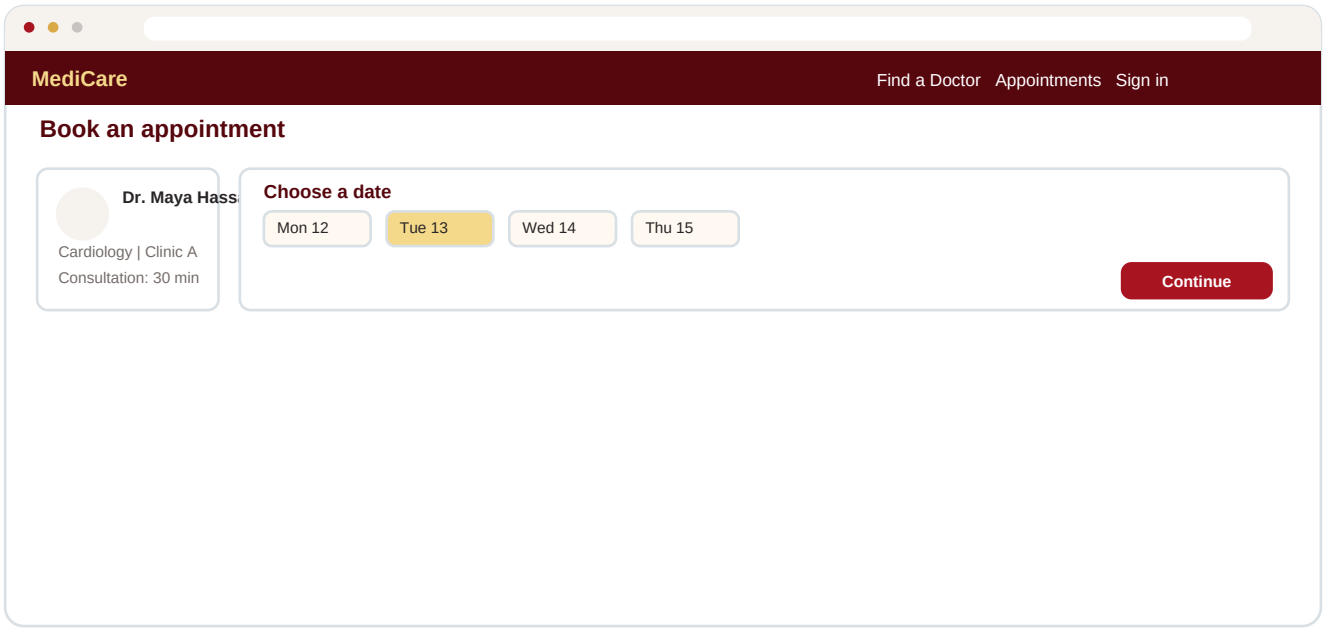
Doctor search results

Keep specialty, location, and availability filters visible. Doctor cards should show name, specialty, location, rating if validated, and a clear profile action.



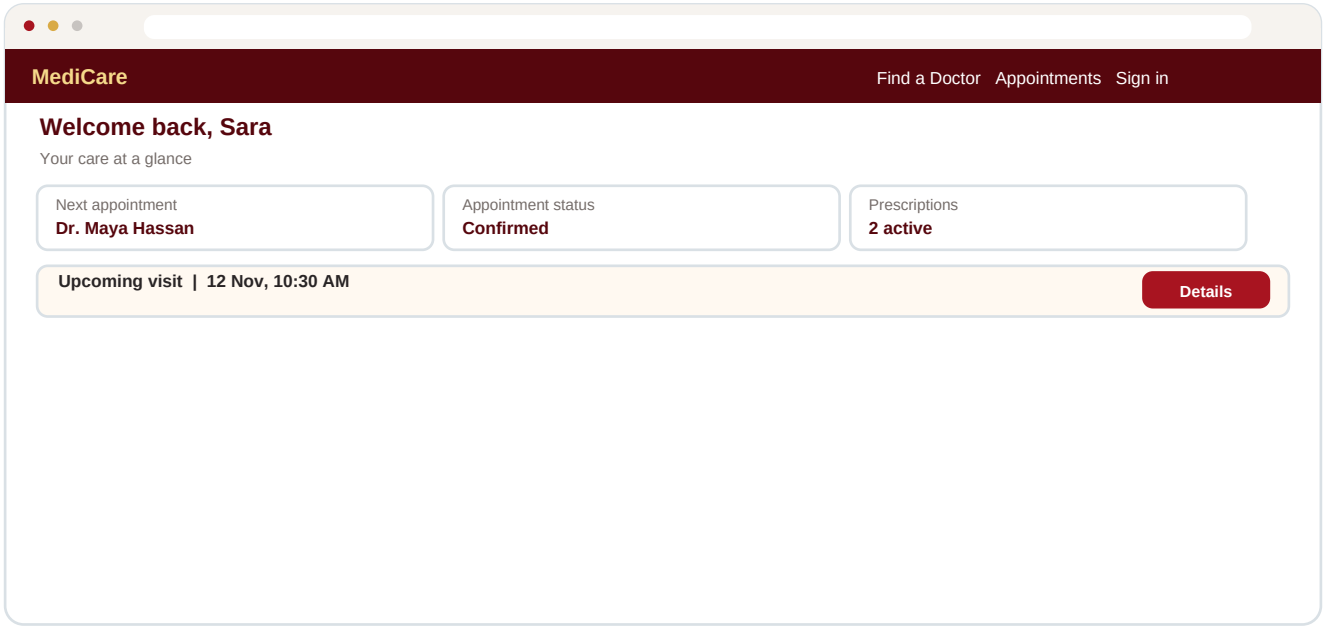
Appointment booking

Show the selected doctor and available dates/times before confirmation. Confirm appointment details and disclose cancellation rules before final submission.



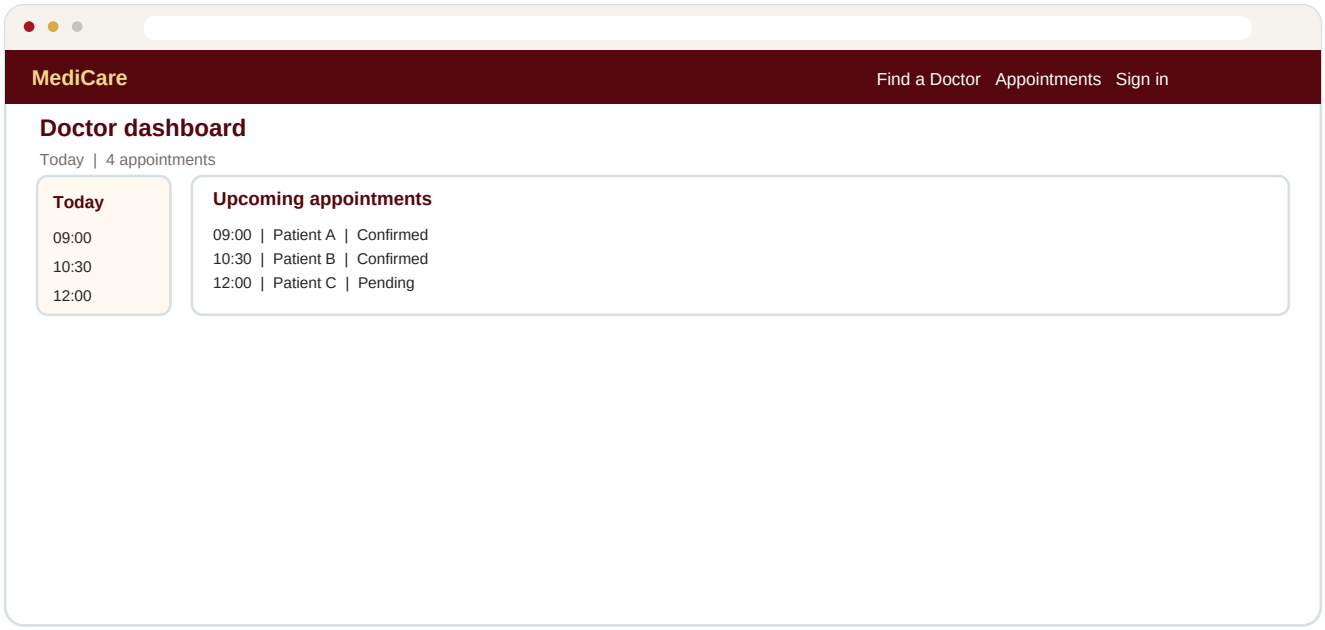
Patient dashboard

Prioritize the next appointment and its status. Provide direct links to appointment history and authorized records.



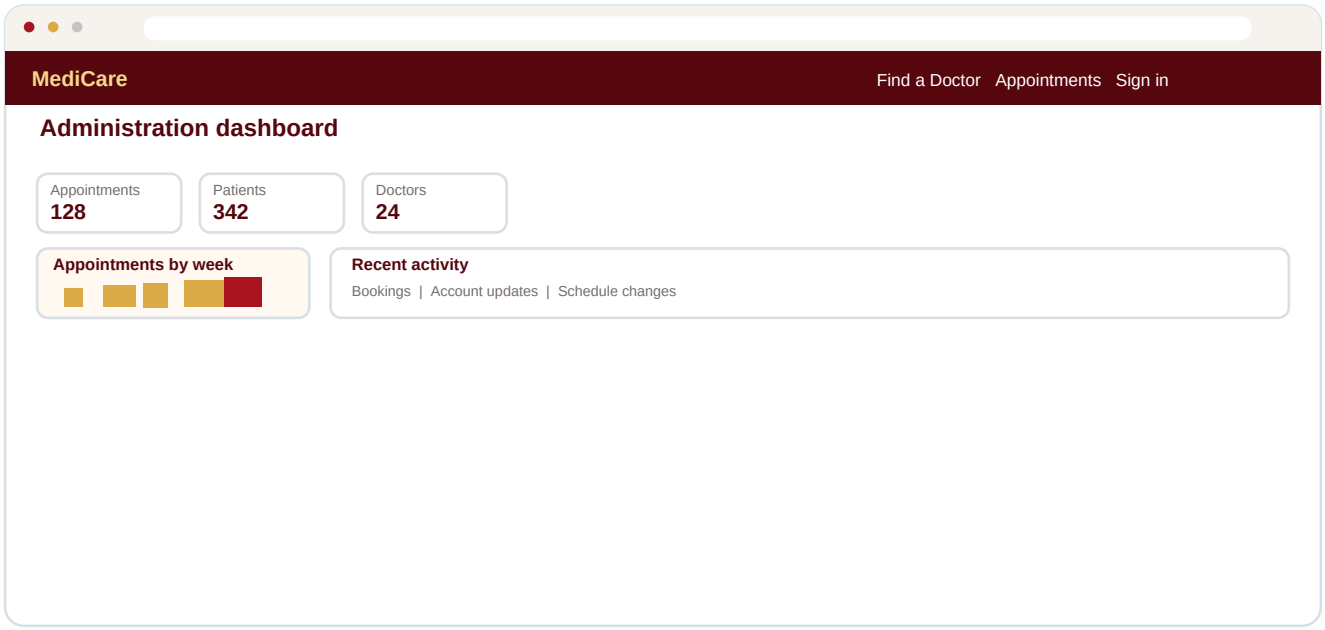
Doctor dashboard

Show today's schedule, appointment statuses, and quick access to relevant patient details.



Administrator dashboard

Use summary metrics, appointment trends, and recent activity to support routine monitoring.



UI/UX Guidelines

Navigation and layout

• Use a consistent top navigation with a clear logo, doctor search, appointment access, and sign-in/account action.

• Use a centered content column with generous spacing; group related information into cards without unnecessary borders.

• Keep primary actions visually distinct and secondary actions quieter. Use one primary CTA per screen where practical.

• On mobile, collapse navigation into an accessible menu and stack search fields and cards vertically.

Forms and feedback

• Place a persistent label above every field; placeholders are examples, not labels.

• Validate inputs on the server and explain errors next to the relevant field in plain language.

• After booking, show a confirmation page with doctor, date, time, location, and next steps.

• Use explicit states: available, selected, booked, cancelled, and unavailable; do not rely on color alone.

• Provide loading, empty, error, and success states for search, calendar, and dashboard views.

Accessibility and readability

• Maintain WCAG 2.2 AA contrast targets for text and controls; verify the final colors in the implemented UI.

• Use charcoal text on ivory/white surfaces and white text on burgundy/crimson buttons. Avoid gold text on white.

• Make every control keyboard reachable with a visible focus indicator and logical tab order.

• Use semantic headings, accessible names for icon-only controls, and descriptive form error messages.

• Use touch targets around 44 by 44 CSS pixels where possible; do not communicate status through color alone.

• Support zoom and responsive reflow without horizontal scrolling at common mobile widths.

Prototype validation checklist

Task	Check
Find a doctor	Can a patient enter a specialty/location and understand the results?
Book an appointment	Can a patient choose a time, review details, and recognize confirmation?
Manage schedule	Can a doctor identify upcoming appointments and availability controls?
Review activity	Can an administrator find appointment totals and recent changes?
Accessibility	Can users navigate by keyboard and identify labels, focus, errors, and statuses?

These are low-fidelity wireframes, not a final visual design. Validate them with representative users, then refine the layout and interactions before implementation.
